Executive Summary: Marketing Data Integrity Audit

Prepared for: CMO / Head of Growth, [Brand Name], a leading Indian D2C fashion brand (anonymised) | Scope: external, browser-level test of Product View to Add to Cart

1. Overview

Every rupee you spend on Meta, Google and Snapchat is judged by the data your site sends back. In my external test of the Product View to Add to Cart journey, that data was broken at several points: duplicate pixel events, events arriving empty, ad domains blocked by policy, and customer identity that appears to be lost at checkout. When the data is wrong, the ad platforms optimise on bad signals, and your reported ROAS stops matching reality.

2. Business Impact

Finding (observed in test session)	Where the money leaks
The Content Security Policy is blocking Google and DoubleClick ad domains (ad.doubleclick.net, googleadservices.com). The Meta Pixel loads, but throws a duplicate event error.	Google Ads remarketing audiences and conversion signals starve; retargeting spend is under-optimised.
The Meta Pixel is firing duplicate events (Console shows 'Duplicate Pixel ID: [redacted]'); invalid currency parameter on Add to Cart	Duplicate events inflate counts; malformed value data weakens ROAS bidding and catalogue ads.
Snapchat pixel (tr6.snapchat.com) and New Relic (bam.nr-data.net) requests fail with ERR_NAME_NOT_RESOLVED	Snapchat spend cannot be attributed or optimised; front-end errors may go unmonitored.
The GA4 add_to_cart event is firing with a null payload (no item ID, no price)	Funnel, product and revenue reporting are unreliable at the exact step that predicts purchase.
CleverTap Add to Cart missing user_email, phone_no, category, model	Abandoned-cart journeys cannot target or personalise; recovery revenue is left on the table.
Empty utm_source / utm_medium / utm_campaign sent to the brand's internal analytics subdomain	Internal attribution cannot tell which campaigns drive traffic, so budget shifts rely on guesswork.
Client tokens (api-token, client-device-token) visible in request headers	Hygiene and risk item: scope, expiry and rotation policy should be reviewed.

3. Likely Root Cause: Headless Checkout Architecture

Checkout runs on GoKwik Headless (**CUSTOM_HEADLESS**), which moves the buyer across a domain boundary. There is a domain-crossing identity break between the GoKwik headless checkout and CleverTap: user emails are captured on the checkout domain but do not appear to sync back to the main CRM. Based on browser-level evidence, this is the likely root cause of the missing CleverTap fields and of weaker abandoned-cart recovery, and it should be confirmed against your internal integration.

4. Recommended Action Plan

Step 1 (Week 1): Fix tracking delivery. Update the CSP to allow the Google Ads and remarketing domains; remove the duplicate Meta Pixel; correct the currency format; verify Snapchat and New Relic endpoints in a clean, extension-free environment and repair what is genuinely failing.

Step 2 (Weeks 1-3): Bridge the checkout data gap. Pass user identifiers from GoKwik back to the main domain (server-side or via callback) and push them to CleverTap, so abandoned-cart flows run on complete profiles.

Step 3 (Weeks 2-4): Clean the data layer. Populate GA4 add_to_cart with item ID, price and currency; persist UTM parameters through the session; review token scope and rotation; add automated monitoring so regressions are caught.

5. Next Steps

Fixing these issues requires three specific architectural changes:

1. CSP Allowlisting: Updating your Content Security Policy headers to permit `*.doubleclick.net` and `*.googleadservices.com` without compromising overall site security.

2. Server-Side Identity Bridging: Implementing a server-to-server (S2S) webhook or `postMessage` callback to securely pass the user's email and phone number from the GoKwik headless checkout domain back to your main domain, and pushing that identity into CleverTap via their `onUserLogin` API.

3. GTM Data Layer Remediation: Re-mapping the GA4 `add_to_cart` data layer push to ensure the `item_id`, `item_name`, and `price` parameters are correctly captured before the tag fires.

I am a Data Forensics Analyst specializing in e-commerce tracking architecture. I have the full technical breakdown (including the exact GTM configurations and the S2S webhook logic) ready to share. If you want to see the implementation roadmap, reply to this message.

Findings reflect an external browser-level test and are subject to confirmation against your internal configuration. No customer data was accessed.
